A liquidity 'black hole' in a large value payment system: What is the impact of a failing participant on its environment and does time matter?

Work in progress

#### Ronald Heijmans and Ellen van der Woerd

20<sup>th</sup> Payments and Settlement System Simulator Seminar Helsinki, Finland

25 and 26 August 2022

Outline

# Sagittarius A\* vs failing LVPS participant

#### Sagittarius A\*

- All mass falling in disappears forever.
- Time is not properly defined.
- Becomes heavier at the cost of other objects in its surroundings.

#### Failing LVPS participant

- All liquidity send to stays there.
- Length of failure not relevant for its own liquidity position
- Gains liquidity at the cost of other participant in its network.

- technical
- software (e.g. update)
- opwer outage

- cyber attack
- human

Ο...

э

#### • This paper aims to:

- identify the Minimum Payment Time Interval (MPTI) a single participant does not send in any payment instruction to be considered an outage and ....
- ... measure the impact of such an outage over time, starting at this MPTI.

< ロ > < 同 > < 回 > < 回 >

## Relevant literature 1/2

Operational outages:

- Klee (2010):
  - detection outages in Fedwire (15 minutes cut off)
- Glowka, Paulick and Schultze (2018):
  - defining outages of longer than 30 minutes with no or low activity for TARGET2 (according to SLA reporting time).
- Arjani and Heijmans:
  - Similar to Glowka et al (2018), but for Canadian LVTS including validation of method.

- A TE N - A TE N

## Relevant literature 2/2

Measuring impact:

- Heijmans and Wendt (2019): failure in terms of liquidity and network impact for banks and FMIs in TARGET2 at daily basis.
- Berndsen and Heijmans (2019): FMI/LVPS level at daily basis.

Timing and free riding:

- Bech and Garratt (2003, 2006) game theoretical model on intentional delay.
- Diehl (2013) free riding in TARGET2-BBK.

A THE A THE

# What do we add to the literature?

- Define participant specific outage time interval (MPTI) instead of fixed cut off (e.g 15 or 30 minutes).
- Measuring the impact over time (instead of fixed time interval, e.g. day).
- Relate liquidity impact to e.g. reserve requirements of the counterparties of failing bank.
- Intraday picture (per hour): keeping track of difference in payment activity (e.g. lunch dips).

3

#### Data

#### • TARGET2-NL (as starting point)

TARGET2 (To extend analysis and include more large banks)

# Which variables from transaction data?

- Introduction date (not settlement)
- Introduction time (during opening hours in microseconds)
- Sender (bic8)
- Receiver (bic8)
- Payment value (EUR)
- Payment type (Eurosystem statistical code)

- A TE N - A TE N

#### Payment type selection:

- MPTI: all except transactions with ancillary systems
  - Settlement organisations and SSS, often direct debits)
- measuring impact to other banks: interbank payments (1.1 and 1.2) only
  - ignore impact to central banks

< ロ > < 同 > < 回 > < 回 >

## Introduction

э

イロト イヨト イヨト イヨト

Results split up:

- Iook at finding the minimum payment time interval (MPTI)
- Iook at measuring the impact (work in progress)

## Concluding remarks MPTI

#### 99.99 percentile as MPTI cut off

- Large banks: MPTI 13 minutes
- Small banks: MPTI 59 minutes
- For large banks: during first hour and last hour longer MPTIs
  - first hour: payments send in before opening hours (introduction vs settlement time)
  - last hour: lower general activity

## Preliminary conclusions

- We define a bank specific minimum time for a potential outage.
- This minimum time varies between different:
  - failing participants (e.g. 13 or 59 minutes).
  - different hours of the day.
- Impact not evenly distributed over counterparties.

A B F A B F

# Who can use the tool we develop?

- Payment system operators (in monitoring liquidity and systemic impact, PFMIs).
- Financial stability experts (measuring systemic impact of large participants).

## Still to do

- Extend analysis to full TARGET2 data (including more large banks).
- Measure impact relative to e.g. reserve requirements.
