Motivation

- The puzzle: high productivity growth attracts resources from abroad and leads to high consumption rates, weakening the external balance
 - Discussion in Gourinchas & Rey (NBER 2013)
 - E.g. Ferrero (JME 2010):

"current levels of US external imbalances versus the G6 are mainly the manifestation of productivity growth and demographic differentials across the two regions" BUT

"China experiences huge [counterfactual] trade deficits over the entire sample, averaging about -11%"

- Literature:
 - Imperfections in financial markets: demand for assets not met by financial markets in emerging economies, resulting in capital outflows (Song et al., AER 2011, Mendoza et al., JPE 2009, Caballero et al., AER 2008)
 - Social security: a country with no pay-as-you-go system has higher saving and experiences capital outflows (Eugeni, JIE 2015)

This paper

The research question:

Can social security, together with demographics, fiscal policy and productivity, explain the dynamics of external imbalances between China and the US between 1980 and 2015?

The approach:

- A dynamic general equilibrium model with a life-cycle structure, productivity growth and fiscal policy *à la* Gertler (1999)/Ferrero (2010)
- Introduce a pay-as-you-go pension system to both countries, endogenous labour supply and distortionary taxation

Results:

• The model predicts positive net foreign asset position and trade balance for China for most years in the sample period

• Key drivers: population ageing and differences in social security across the countries

The model

- Two large economies consisting of households, firms and the government
- Firms produce the single (traded) good with Cobb-Douglas production technology
- Government pays pension benefits and spends with tax income and debt
- An international financial market with no frictions
 - > The market clearing condition pins down the world real interest rate

Life cycle structure:

- Workers N_t^w
 - In period t, the probability to stay in labour force is $\omega_{t,t+1}$
 - Number of new workers born in period t: $(1 \omega_{t,t+1} + n_{t,t+1}) N_t^w$
 - Law of motion for aggregate number of workers: $N_{t+1}^{w} = (1 - \omega_{t,t+1} + n_{t,t+1}) N_{t}^{w} + \omega_{t,t+1} N_{t}^{w} = (1 + n_{t,t+1}) N_{t}^{w}$
- Retirees N^r_t
 - In period t, the probability to survive to the next period is $\gamma_{t,t+1}$
 - Law of motion for retirees: $N_{t+1}^r = (1 \omega_{t,t+1}) N_t^w + \gamma_{t,t+1} N_t^r$

The model Households: workers

 A worker born in period j chooses consumption C^{jw}_t, saving A^{jw}_{t+1} and labour supply l^{jw}_t to maximize

$$V_{t}^{jw} = \left\{ \left[\left(C_{t}^{jw} \right)^{\nu} \left(1 - l_{t}^{jw} \right)^{1-\nu} \right]^{\rho} + \beta \left[\omega_{t,t+1} V_{t+1}^{jw} + \left(1 - \omega_{t,t+1} \right) V_{t+1}^{jr} \right]^{\rho} \right\}^{\frac{1}{\rho}}$$

・ロト ・ 目 ・ ・ ヨト ・ ヨ ・ うへつ

subject to

$$\mathcal{A}_{t+1}^{jw} = \mathcal{R}_t \mathcal{A}_t^{jw} + \mathcal{W}_t \mathcal{I}_t^{jw} \left(1 - \tau_t\right) - C_t^{jw}$$

• Consumption is a fraction of the present value of wealth $C_{t}^{jw} = \pi_{t}(R_{t}A_{t}^{jw} + H_{t}^{jw} + P_{t}^{jw})$

The model

Households: retirees

• A retiree born in period j and retired in period i chooses consumption $C_t^{jr}(i)$, saving $A_{t+1}^{jr}(i)$ and labour supply $l_t^{jr}(i)$ to maximize

$$V_t^{jr}(i) = \left\{ \left[\left(C_t^{jr}(i) \right)^{\nu} (1 - l_t^r)^{1 - \nu} \right]^{\rho} + \beta \gamma_{t,t+1} \left(V_{t+1}^{jr}(i) \right)^{\rho} \right\}^{\frac{1}{\rho}}$$

subject to

$$A_{t+1}^{jr}(i) = R_t A_t^{jr}(i) / \gamma_{t-1,t} + W_t \xi l_t^{jr}(i) (1 - \tau_t) + S_t^{jr}(i) - C_t^{jr}(i)$$

Preferences

Consumption is a fraction of the present value of wealth

$$C_t^{jr}(i) = \varepsilon_t \pi_t \left(R_{W,t} A_t^{jr}(i) / \gamma_t + H_t^{jr}(i) + P_t^{jr}(i) \right)$$

A dynamic analysis: 1980-2015

• Simulate the calibrated model for China-US for 1980-2015

- For China, a period of transition from a centrally planned economy to a market economy & integration to the world economy
- Coincides with the formation of large external imbalances in China and the US
- The simulation captures:
 - Demogaphic factors: permanent and temporary differences
 - Public pension expenditures and other government expenditures: permanent and temporary differences

- Productivity fluctuations: temporary differences
- Two solution methods: standard deterministic simulation (I) and deterministic simulation with learning (II)

Demographic trends

Source: UN World population prospects, The 2015 Revision

Model (simulation I):

- Population growth slows down: $n_{1980}^{w,US} = n_{1980}^{w,China} = 2.15\% \rightarrow n_{2015}^{w,US} = n_{2015}^{w,China} = 0.5\%$
- Life expectancy increases:

$$\gamma_{1980}^{US} = 0.894 \ (74.3 \ \text{years}) \rightarrow \gamma_{2015}^{US} = 0.932 \ (78.9 \ \text{years});$$

 $\gamma_{1980}^{China} = 0.764 \ (67.5 \ \text{years}) \rightarrow \gamma_{2015}^{China} = 0.925 \ (75.4 \ \text{years})$

Simulation I: China-US trade balance and net foreign asset position 1980-2015

Effects of demographic trends

▲ロト ▲園 ト ▲ 臣 ト ▲ 臣 ト 一臣 - のへ(で)

Social security

China

- Ourrent II-tier system since 1998:
 - I) public basic pension funded on a pay-as-you-go basis, defined benefit
 - II) mandatory employee contribution to a second-tier plan
- Coverage: 27.7 % of population aged 15-65 (OECD 2015)
- Defined benefit public pension scheme "Social Security", partly funded (85% of insurance income from payroll taxes in 2015, SSA 2017)
- Coverage: 71.4 % of population aged 15-65 (OECD 2015)

(日) (四) (日) (日) (日)

Model (simulation I):

Social security expenditures (public pension spending) permanently higher in the US: $s_{IJS 1980} = 6\% \rightarrow s_{IJS 2015} = 7\%$ $s_{China,1980} = s_{China,2015} = 2\%$

Simulation I: China-US trade balance and net foreign asset position 1980-2015

Effects of demographic trends, social security and government expenditures

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ ─臣 ─の�?

Productivity growth

• By assumption, no permanent changes in productivity growth $x_{US,1980} = x_{China,1980} = x_{US,2015} = x_{China,2015} = 1\%$

(日)

э

Simulation I: China-US trade balance and net foreign asset position 1980-2015

Effects of demographic trends, social security, government expenditures and TFP growth

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Simulation II: Deterministic solution with learning

- Alternative solution: in each period, there are unanticipated innovations in exogenous variables
 - After the shock, TFP and government expenditures are assumed to slowly converge back to the permanent levels
 - Demographic variables are assumed to evolve as predicted by the most recent vintage of the UN population forecast

- The transition paths of all variables are compiled from different rounds of simulation
 - Compiled series of exogenous variables exactly match the data

Simulation II: China-US trade balance and net foreign asset position 1980-2015

Effects of demographic trends, social security, government expenditures and TFP growth

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 - のへで

Conclusions

- The paper focuses on the effects of demographics and social security on aggregate savings, consumption, investment and the external balance
 - It abstracts from financial market frictions; but offers a complementary explanation
- In the model, fast increase in life expectancy in China helps to explain why the country has accumulated foreign assets in the past decades
- Low level of social security can explain why the savings in China are high despite the relatively young population
- The effect of social security and demographics is quantitatively significant
 - The model predicts a trade surplus for China for the majority of the years in the simulation

Calibration

Parameter		Model
β	discount factor	0.99
α	labour share	$\frac{2}{3}$
δ	discount rate	0.2
σ	elasticity of intertemporal substitution	0.55
ξ	productivity of a unit of labour, retiree to worker	0.5
V	elasticity of period utility with respect to consumption	0.7
x	growth rate of technology	0.01
п	population growth rate	0.0215
γ ₁ / γ ₂	probability to survive (if retired)	0.894/0.764
ω_1 / ω_2	probability to stay in the labour force	0.978/0.977
b_1/b_2	government debt, % of gdp	0
g_1/g_2	government spending, % of gdp	0.155/0.144
s_1/s_2	social security spending, % of gdp	0.06/0.02
ϕ	adjustment cost parameter	3
$\frac{XN}{X^*N^*}$	relative size of the countries	0.99

Calibration for the initial steady state between the US and China (1980). Data sources: see appendix.

Dynamic equations

• Retirees' marginal propensity to consume out of wealth is

$$\varepsilon_t \pi_t = 1 - \frac{\varepsilon_t \pi_t}{\varepsilon_{t+1} \pi_{t+1}} \gamma_{t,t+1} \left(\frac{W_t (1 - \tau_t)}{W_{t+1} (1 - \tau_{t+1})} \right)^{\rho \sigma (1 - \nu)} \beta^{\sigma} (R_{t+1})^{\rho \sigma}$$

• Workers' marginal propensity to consume out of wealth is

$$\pi_t = 1 - \frac{\pi_t}{\pi_{t+1}} \left(\frac{W_t (1 - \tau_t)}{W_{t+1} (1 - \tau_{t+1})} \right)^{\rho \sigma (1 - \nu)} \beta^{\sigma} (R_{W, t+1} \Omega_{t+1})^{\sigma - 1}$$

•

-

Why Epstein-Zin preferences?

- There are idiosyncratic risks in the model, that may complicate both the derivation and aggregation of individual decision rules (Gertler 1999) →mitigate the idiosyncratic risks
- Death risk: retirees face a risk because of the uncertainty of the time of death
 - Eliminated by assuming a perfect annuities market following Yaari (1965) and Blanchard (1985), which provides perfect insurance against this risk

Petirement risk: the uncertainty of retirement time causes a risk to workers' wage income

Eliminate by assuming Epstein-Zin preferences, which allow to separate income risk aversion and elasticity of intertemporal subsitution, and assume that µ=1: agents are risk neutral with respect to income risk

$$V_t^z = \left\{ \left[(C_t^z)^v (1 - l_t^z)^{1-v} \right]^\rho + \beta_{t,t+1}^z \left[E_t (V_{t+1} \mid z)^\mu \right]^{\frac{\rho}{\mu}} \right\}^{\frac{1}{\rho}} , \ z = \{w, r\} \ .$$

- μ : parameter for risk aversion
- ho : curvature parameter $\sigma = rac{1}{1ho}$ parameter for intertemporal substitution

Why Epstein-Zin preferences?

- This yields individual decision rules that are linear in wealth and independent of individual characteristics
 - All retirees and workers have the same marginal propensity to consume (mpc)
- In order to solve for aggregate consumption by retirees and workers, one (only) needs to keep track of the distribution of wealth between the groups ("the Gertler trick")
- Preferences allow to maintain elasticity of intertemporal substitution :
 - Agents care about consumption smoothing \rightarrow Assume: $\rho = x$ ie σ is finite
 - σ is an important parameter in determining the quantitative effects of social security and population ageing

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Steady state effects of population ageing

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Steady states for $0.92 \leq \gamma_2 \leq 0.9319$ and $\gamma_1 = 0.9319$ (blue line = US and red dotted line = China).

Effects of population ageing

- Retirees' and workers' marginal propensities to consume fall because of higher life expectancy
- Composition effect increases consumption
 - ▶ The share of retirees increases: the old age dependency ratio in the steady state is $\psi = \frac{1-\omega}{1+n-\gamma}$ increases
 - $\varepsilon_t = \frac{mpc, retirees}{mpc, workers} \ge 1$: out of the present value of lifetime wealth, retirees consume more than workers

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

• The fall in the mpc's quantitatively dominates over the composition effect

Steady state effects of social security

Steady states for $0.02 \le s_2 \le 0.06$ and $s_1 = 0.06$ with distortionary taxes (blue line = US and red dotted line = China).

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Government expenditures

Source: World Bank, World Development Indicators 2016.

Model (simulation I):

 Steady state government expenditures permanently higher in the US: gU5,1980 = gU5,2015 = 15.5% gChina,1980 = gChina,2015 = 14.4%
