

BANK FOR INTERNATIONAL SETTLEMENTS

Money and coordination

Hyun Song Shin*

Bank for International Settlements

Bank of Finland/CEPR conference "Money in the digital age"

Helsinki, 13 June 2018

* The views expressed here are mine, not necessarily those of the Bank for International Settlements.

Economics of money

- ▶ Money as memory (Kocherlakota (JET 1998))
 - ▶ Money substitutes for a shared ledger recording the full history of who has paid what to whom
- ▶ Inherently worthless tokens perform better in eliciting cooperation than keeping score individually
 - ▶ Araujo and Guimaraes (RED 2017): money as a record (of goods delivered/services rendered) is more robust to imperfect information
 - ▶ Camera and Casari (AEJ Micro 2014) shows experimental evidence
- ▶ Maintaining identical copies of a ledger recording the full history of payments brings us to the discussion on cryptocurrencies

Assessing cryptocurrencies

- ▶ Focus on the economics, not the technology
 - ▶ How well do they serve as money?
 - ▶ Can they perform the role played by today's monetary system?
- ▶ Two limitations loom large
 - ▶ Lacks scalability
 - ▶ Lacks guarantee of finality

Ecosystem

- ▶ Users who make and receive payments
- ▶ Miners who update the ledger

- ▶ Two papers in this conference:
 - ▶ Game between the miners (Biais, Bisière, Bouvard and Casamatta (2017))
 - ▶ Game between the users (Huberman, Leshno and Moelllemi (2017))

Economy with high value payments

Finality of payments

- ▶ Finality refers to the irreversible and unconditional nature of the payment
 - ▶ Cornerstone of a well-functioning payment system
 - ▶ Conventional monetary system does this ultimately through the settlement on the central bank's balance sheet.
- ▶ Finality is especially important when one payment is dependent on another
 - ▶ Otherwise, a buyer “pays” when there is no money
 - ▶ Possibility of cascade of voided transactions

Finding consensus in a decentralised system

- ▶ How to achieve consensus?
- ▶ How to achieve consensus *good enough for action* when there is something at stake?

- ▶ These are quite different questions
 - ▶ Halpern and Moses (JACM 1990)
 - ▶ Rubinstein (AER 1989)
 - ▶ Morris, Rob and Shin (Econometrica 1995)

Two node problem

Restatement of the coordinated attack problem (Halpern and Moses (1990))

- ▶ Two nodes in a distributed system must certify a payment as being genuine or not
- ▶ Two states:
 - ▶ Genuine (G), with probability $1 - \delta$
 - ▶ Fraudulent (F), with probability δ
- ▶ Node 1 knows whether G or F is the case; Node 2 does not
 - ▶ However, Nodes 1 and 2 can send messages and confirmations to each other
 - ▶ Messages get through with probability $1 - \varepsilon$, with $\varepsilon < \delta$

Payoffs

- ▶ Payoffs in state G

	Confirm	Reject
Confirm	1, 1	$-M, 0$
Reject	0, $-M$	0, 0

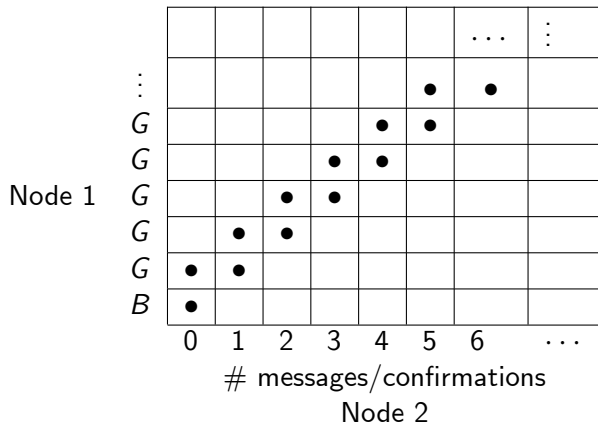

$M > 1$

- ▶ Payoffs in state F

	Confirm	Reject
Confirm	$-M, -M$	$-M, 0$
Reject	0, $-M$	0, 0

Confirming genuine payments and rejecting fraudulent ones are best for both nodes

Strategy space

Node 1 rejects in state F

Node 2 rejects when no message arrives

Expected payoff to confirm is $\frac{(1-\delta)\varepsilon - \delta M}{(1-\delta)\varepsilon + \delta} < 0$

Node 1 rejects when message is sent but no confirmation arrives

Either message did not get through ($\frac{(1-\delta)\epsilon}{(1-\delta)\epsilon + (1-\delta)\epsilon(1-\epsilon)}$) or confirmation did not get through, and the former is more likely

Expected payoff to confirm is $p \cdot 1 - (1-p)M < 0$, since $p < 0.5$ and $M > 1$

Node 2 rejects when confirmation is sent but no re-confirmation arrives

Either confirmation did not get through or re-confirmation did not get through, and the former is more likely

Expected payoff to confirm is $p \cdot 1 - (1 - p) M < 0$, since $p < 0.5$ and $M > 1$

Unique (dominance solvable) equilibrium is for both nodes to reject irrespective of number of confirmations

						...	⋮	
⋮					×	×		
G				×	×			
G			×	×				
Node 1			×	×				
G		×	×					
G	×	×						
F	×							
	0	1	2	3	4	5	6	...
	# messages/confirmations							
	Node 2							

Stark difference between **consensus** and **consensus strong enough for action**

Concentration of mining pools

A "hard fork" in the blockchain

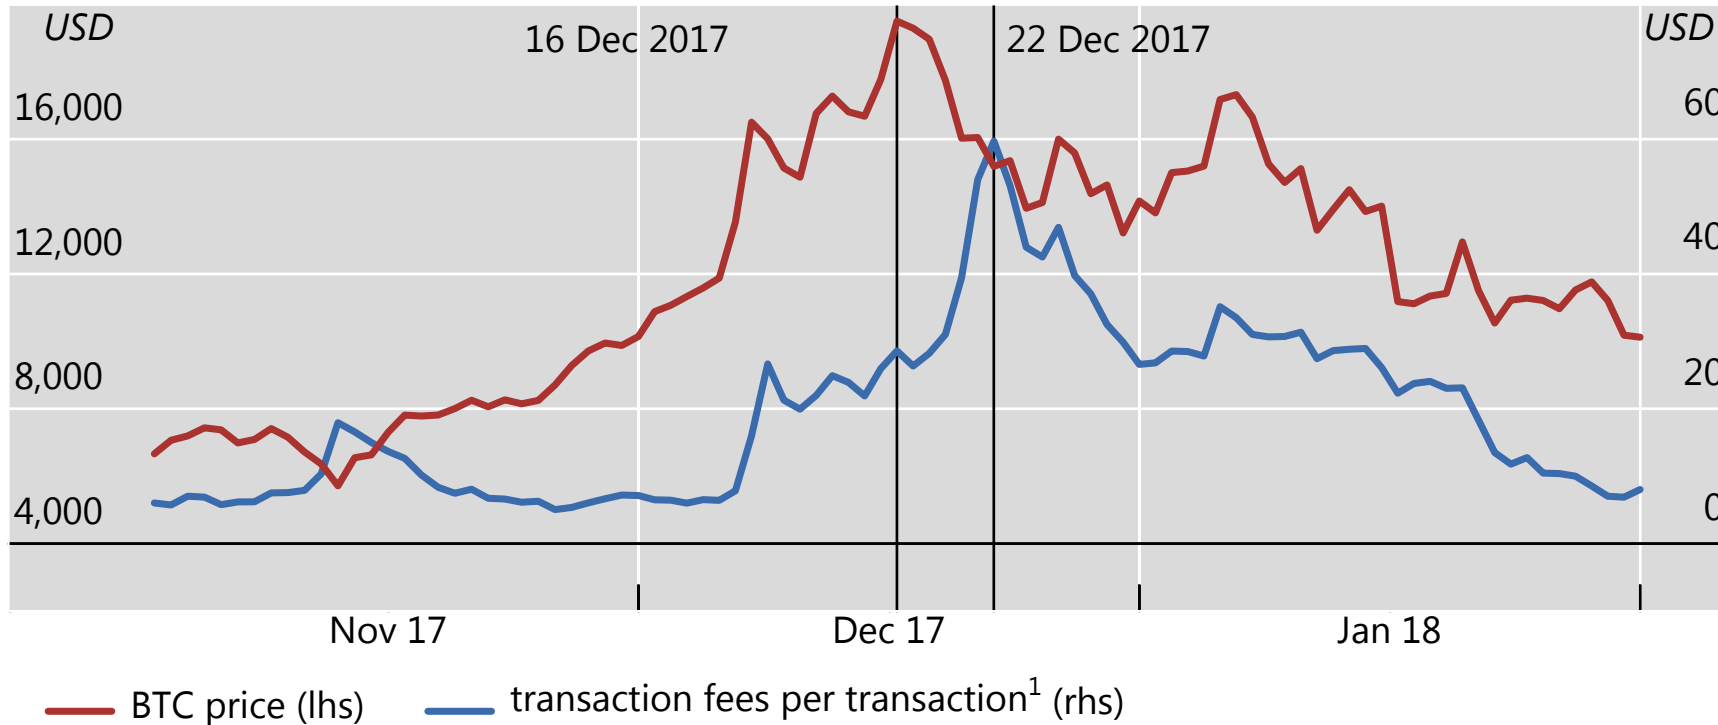

Bitcoin price and transaction fees

¹ Transaction fees per transaction are computed by dividing the total transaction fees in a given day by the number of daily confirmed Bitcoin transactions.

Summing up

- ▶ Economics of cryptocurrencies pose questions just as hard as for illicit activities and consumer protection
- ▶ Outsourcing trust to selfish book-keepers results in a congestion game, not a coordination game
 - ▶ The more the sorrier, instead of the more the merrier
- ▶ Outsourcing trust to selfish book-keepers cannot guarantee finality, the cornerstone of a payment system
 - ▶ Not simply about technical agreement, but about accountability
