Introduction

- Recent economic expansions: Monetary easing failed to stimulate wage growth despite strong employment growth
- Flattening of the Wage Phillips Curve
- · Labor market power is very elevated in the U.S.
 - Wages \approx 30% "marked down" below the marginal product of labor (Hershbein, Macaluso, Yeh; 2019)

• **This paper**: implications of labor market power for monetary policy transmission

• Labor Market Power strengthens the labor demand effects of monetary policy

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のへで 3/22

- · The effect is stronger for non-skilled workers
- · But no effect on wage growth effects of monetary policy
 - High LMP firms' wages respond in the same way
- \Rightarrow Labor market power offers partial explanation for wageless recovery

Intuition

- Results consistent with a search and matching model where hiring can be adjusted using two margins:
 - · Higher wages attract more workers, and...
 - Posting multiple vacancies also attracts more workers
- Labor Market Power:
 - · More efficient matching, i.e. vacancies are more visible or

- Lower vacancy posting costs
- \Rightarrow Adjust vacancies relative to wages disproportionately

Model Sketch

- Firms hire by posting wages and multiple vacancies, represented by hiring function h(w, v), for simplicity assume hiring happens every period
- FOC for the firm:

- Labor market power: (i) lower costs of posting vacancies (c) or (ii) better visibility (larger h'_v)
- MP easing shock ⇒ Labor market power amplifies the response of vacancies and hiring without a disproportional increase in wages

Data

Burning Glass Technology

- $\circ~$ Near universe of online vacancy postings: \approx 250 million vacancies from over 45,000 websites, over \approx 10 years
- 70% of all U.S. online vacancies
- Industry and occupation IDs
- Job requirements (e.g. education, skills)
- Geographical breakdown, establishment level data
- Posted wages
- Monetary Policy shocks using Jarocinski and Karadi (2020).

This paper: focuses on MP shocks but controls for information component 💽

Definition: Labor market power

- Cournout competition model of Berger, Herkenhoff and Mongey (2022): Share of total payroll of each firm
 - In the spirit of Atkeson and Burstein (2008)
- Vacancy Share: Share of vacancies posted by a single firm in a local labor market
- We define a labor market as a U.S. census commuting zone
- · Use cumulative share to allow for inclusion of smaller firms

Vacancy Share_{*i*,*c*,*t*} =
$$\frac{\sum_{\tau \leq t} v_{i,c\tau}}{\sum_{\tau \leq t} \sum_{i} v_{i,c\tau}}$$

Wages decline with higher vacancy shares

Confirmed in regressions after controlling for vacancy characteristics

Log Vacancies_{*i*,*c*,*t*} = $\alpha + \beta$ MP easing_{*t*}×Labor Market Power_{*i*,*c*,*t*-1}+ θ X_{*i*,*c*,*t*}+ γ _{*i*,*t*}+ γ _{*c*,*t*}+ ε _{*i*,*c*,*t*}

 $X_{i,c,t}$ includes the Fed. information shock and its interactions with the market share $\gamma_{i,t}$ - firm-time fixed effects

 $\gamma_{c,t}$ - commuting zone - time fixed effects

- Firm-Time fixed effects absorb any firm-level shocks, such as productivity, increase in funding, changes in stock prices
- Commuting zone Time fixed effects absorb any regional variation, such as regional demand shocks

Firms with more labor market power are more responsive to MP

Heterogeneity

 Burning Glass provides granular data on postings, including on skill and education requirements, so far we focused on college education and software skills

 $\approx 40\%$ of college vacancies, $\approx 28\%$ of software vacancies, correlation $\approx 29\%$

Log Vacancies_{*i*,*c*,*t*,*j*} = α + β MP easing_{*t*} × Labor Market Power_{*i*,*c*,*t*-1}+ δ MP easing_{*t*} × Labor Market Power_{*i*,*c*,*t*-1} × Type_{*j*} + θ X_{*i*,*c*,*t*+ + $\gamma_{i,t}$ + $\gamma_{c,t}$ + $\varepsilon_{i,c,t,j}$}

- The **significance** of the triple interaction coefficient reveals whether there is significant heterogeneity
- The **opposite signs** of double and triple interaction would mean that the effect is weaker for the [Type = 1]

Heterogeneity across vacancy types

Wage Response to Monetary Policy Easing

◆□ ▶ < @ ▶ < E ▶ < E ▶ ○ 2 ○ ○ (0/22)</p>

Geography of Labor Market Power

Phillips Curve Implication

Conclusion

- · Labor market power strengthens the employment effects of monetary policy
- · Especially for low-skilled workers
- The capacity of monetary policy to influence wages might be more limited, especially for firms that have high labor market power
- Results help explain modest increase in wages in the post-GFC recovery, while unemployment significantly declined ("wageless recovery")
- Ongoing tightening of U.S. monetary policy could have important implications for income inequality across skills groups and regions
